

- 3 (a) State what is meant by two objects being in thermal equilibrium.

.....

.....

..... [2]

- (b) An insulated container with negligible specific heat capacity contains a mass of 63 g of water at an initial temperature of 78.0 °C.

A thermistor with a mass of 8.5 g is at an initial temperature of 25.0 °C. The thermistor is connected into a circuit containing an ammeter that is accurately calibrated to give readings of temperature in °C.

The thermistor is immersed in the water. When thermal equilibrium is reached, the ammeter indicates a temperature of 76.8 °C.

- (i) Explain why the thermistor does not measure the temperature as 78.0 °C.

.....

.....

..... [2]

- (ii) The specific heat capacity of water is $4.2 \text{ J g}^{-1} \text{ K}^{-1}$.

Calculate a value for the specific heat capacity, in $\text{J g}^{-1} \text{ K}^{-1}$, of the material of the thermistor.

specific heat capacity = $\text{J g}^{-1} \text{ K}^{-1}$ [3]

- (c) Suggest, with a reason, how the initial temperature of the water in **3(b)** could be measured more accurately than using the thermistor in **3(b)**.
